## Syntax

Let $\mathcal{V} \triangleq\left\{\mathrm{V}, \mathrm{V}_{1}, \mathrm{~V}_{2}, \ldots\right\}$ be a finite set of variables.
Let $\mathbb{Z} \triangleq\{\mathcal{Z}, \ldots\}$ be the set of relative numbers.
Expressions are polynomial of variables $\mathcal{V}$.

$$
\mathrm{E}::=z|\mathrm{~V}| \mathrm{E}+\mathrm{E} \mid \mathrm{E} \times \mathrm{E}
$$

Programs are given by the following grammar:

$$
\begin{aligned}
\mathrm{P}:= & \text { skip } \\
\mid & P ; P \\
& \mathrm{~V}:=\mathrm{E} \\
\mid & \text { if }(\mathrm{V} \geq 0)\{P\} \text { else }\{P\} \\
& \text { while }(\mathrm{V} \geq 0)\{P\}
\end{aligned}
$$

## Semantics

We define the semantics $\llbracket \mathrm{P} \rrbracket \in \mathcal{F}((\mathcal{V} \rightarrow \mathbb{Z}) \cup \Omega)$ of a program P :

- $\llbracket$ skip $\rrbracket(\rho)=\rho$,
- $\llbracket P_{1} ; P_{2} \rrbracket(\rho)= \begin{cases}\Omega & \text { if } \llbracket P_{1} \rrbracket(\rho)=\Omega \\ \llbracket P_{2} \rrbracket\left(\llbracket P_{1} \rrbracket(\rho)\right) & \text { otherwise }\end{cases}$
- $\llbracket V:=\mathrm{E} \rrbracket(\rho)= \begin{cases}\Omega & \text { if } \rho=\Omega \\ \rho[\mathrm{V} \mapsto \bar{\rho}(\mathrm{E})] & \text { otherwise }\end{cases}$
- $\llbracket$ if $(V \geq 0)\left\{P_{1}\right\}$ else $\left\{P_{2}\right\} \rrbracket(\rho)= \begin{cases}\Omega & \text { if } \rho=\Omega \\ \llbracket P_{1} \rrbracket(\rho) & \text { if } \rho(V) \geq 0 \\ \llbracket P_{2} \rrbracket(\rho) & \text { otherwise }\end{cases}$
- $\llbracket$ while $(V \geq 0)\{P\} \rrbracket(\rho)= \begin{cases}\Omega & \text { if } \rho=\Omega \\ \rho^{\prime} & \text { if }\left\{\rho^{\prime}\right\}=\left\{\rho^{\prime} \in \operatorname{Inv} \mid \rho^{\prime}(\mathbf{V})<0\right\} \\ \Omega & \text { otherwise }\end{cases}$ where $\operatorname{Inv}=\operatorname{Ifp}\left(X \mapsto\{\rho\} \cup\left\{\rho^{\prime \prime} \mid \exists \rho^{\prime} \in X, \rho^{\prime}(\mathrm{V}) \geq 0\right.\right.$ and $\left.\left.\rho^{\prime \prime} \in \llbracket \mathrm{P} \rrbracket\left(\rho^{\prime}\right)\right\}\right)$.

## Flow of information

Given a program $P$, we say that the variable $V_{1}$ flows into the variable $V_{2}$ if, and only if, the final value of $V_{2}$ depends on the initial value of $V_{1}$, which is written $V_{1} \Rightarrow{ }_{p} V_{2}$.

More formally,
$V_{1} \Rightarrow V_{p} V_{2}$ if and only if there exists $\rho \in \mathcal{V} \rightarrow \mathbb{Z}, z, z^{\prime} \in \mathbb{Z}$ such that one of the following three assertions is satisfied:

1. $\llbracket \mathrm{P} \rrbracket\left(\rho\left[\mathrm{V}_{1} \mapsto z\right]\right) \neq \Omega, \llbracket \mathrm{P} \rrbracket\left(\rho\left[\mathrm{V}_{1} \mapsto z^{\prime}\right]\right) \neq \Omega$, and $\llbracket \mathbb{P} \rrbracket\left(\rho\left[V_{1} \mapsto z\right]\right)\left(V_{2}\right) \neq \llbracket \mathrm{P} \rrbracket\left(\rho\left[V_{1} \mapsto z^{\prime}\right]\right)\left(V_{2}\right)$;
2. $\llbracket \mathrm{P} \rrbracket\left(\rho\left[\mathrm{V}_{1} \mapsto z\right]\right)=\Omega$ and $\llbracket \mathrm{P} \rrbracket\left(\rho\left[\mathrm{V}_{1} \mapsto z^{\prime}\right]\right) \neq \Omega$;
3. $\llbracket \mathbb{P} \rrbracket\left(\rho\left[\mathrm{V}_{1} \mapsto z\right]\right) \neq \Omega$ and $\llbracket \mathrm{P} \rrbracket\left(\rho\left[\mathrm{V}_{1} \mapsto z^{\prime}\right]\right)=\Omega$.

## Syntactic approximation (tentative)

Let $P$ be a program.

We define the following binary relation $\rightarrow_{p}$ among variables in $\mathcal{V}$ : $V_{1} \rightarrow_{p} V_{2}$ if and only if there is an assignement in $P$ of the form $V_{2}:=E$ such that $V_{1}$ occurs in $E$.

Does $\mathrm{V}_{1} \Rightarrow{ }_{\mathrm{p}} \mathrm{V}_{2}$ imply that $\mathrm{V}_{1} \rightarrow_{\mathrm{p}}^{*} \mathrm{~V}_{2}$ ?

## Counter-example

We consider the following progrem P :

$$
\begin{array}{r}
\mathrm{P}::=\text { if }\left(\mathrm{V}_{1} \geq 0\right) \\
\left\{\mathrm{V}_{2}:=0\right\} \\
\text { else } \\
\left\{\mathrm{V}_{2}:=1\right\}
\end{array}
$$

For any $\rho \in \mathcal{V} \rightarrow \mathbb{Z}$, we have $\llbracket \mathrm{P} \rrbracket\left(\rho\left[V_{1} \mapsto 0\right]\right)\left(V_{2}\right)=0$; but, $\llbracket \mathrm{P} \rrbracket\left(\rho\left[\mathrm{V}_{1} \mapsto 1\right]\right)\left(\mathrm{V}_{2}\right)=1$; so $\mathrm{V}_{1} \Rightarrow \mathrm{p} \mathrm{V}_{2}$;
But $\mathrm{V}_{1} \rightarrow{ }^{*}{ }_{\mathrm{p}} \mathrm{V}_{2}$.

## Syntactic approximation (tentative)

For each program point $p$ in $P$,
we denote by test(p) the set of variables which occur in the guards of tests and while loops the scope of which contains the program point $p$.

We define the following binary relation $\rightarrow$ among variables in $\mathcal{V}$ :
$V_{1} \rightarrow_{p} V_{2}$ if and only if there is an assignement in $P$ of the form $V_{2}:=E$ at program point $p$ such that:

1. either $V_{1}$ occurs in $E$;
2. or $\mathrm{V}_{1} \in \operatorname{test}(\mathrm{p})$.

Does $\mathrm{V}_{1} \Rightarrow{ }_{p} \mathrm{~V}_{2}$ imply that $\mathrm{V}_{1} \rightarrow_{\mathrm{p}}^{*} \mathrm{~V}_{2}$ ?

## Counter-example

We consider the following progrem P :

$$
P::=\text { while }\left(\mathrm{V}_{1} \geq 0\right)\{\text { skip }\}
$$

For any $\rho \in \mathcal{V} \rightarrow \mathbb{Z}$, we have $\llbracket \mathbb{P} \rrbracket\left(\rho\left[\mathrm{V}_{1} \mapsto-1\right]\right) \neq \Omega$;
but, $\llbracket \mathbb{P} \rrbracket\left(\rho\left[\mathrm{V}_{1} \mapsto 0\right]\right)=\Omega$;
so $\mathrm{V}_{1} \Rightarrow \mathrm{p} \mathrm{V}_{2}$;
But $\mathrm{V}_{1} \nrightarrow{ }_{\mathrm{p}}^{*} \mathrm{~V}_{2}$.

## Approximation of the information flow

So as to get a sound approximation of the information flow, we have to consider that a variable that is tested in the guard of a loop may flow in any variable.

We define the following binary relation $\rightarrow_{p}$ among variables in $\mathcal{V}$ :
$V_{1} \rightarrow V_{2}$ if and only if there is an assignement in $P$ of the form $V_{2}:=E$ at program point $p$ such that:

1. either $V_{1}$ occurs in $E$;
2. or $V_{1}$ is tested in the guard of a loop;
3. or $\mathrm{V}_{1} \in \operatorname{test}(\mathrm{p})$.

Theorem 1 If $\mathrm{V}_{1} \Rightarrow_{\mathrm{p}} \mathrm{V}_{2}$, then $\mathrm{V}_{1} \rightarrow_{\mathrm{p}}^{*} \mathrm{~V}_{2}$ !

## Limitations

The approximation is highly syntax-oriented.

- It is context-insensitive;
- It is very rough in the case of while loop,
$\Longrightarrow$ we could show statically that some loops always terminate to avoid fictitious dependencies;
- we could detect some invariants to avoid fictitious dependencies.

Other forms of attacks could be modeled in the semantics: an attacker could observe:

- computation time;
- memory assumption;
- heating.
(attacks cannot be exhaustively specified).
