

# Relational Numerical Abstract Domains

MPRI 2–6: Abstract Interpretation,  
application to verification and static analysis

Antoine Miné

Year 2024–2025

Course 4  
14 October 2024

# Outline

- The need for relational domains
- Presentation of a few relational numerical abstract domains
  - linear equality domain
  - polyhedra domain
  - weakly relational domains: zones, octagons
- Bibliography

# Shortcomings of non-relational domains

---

# Accumulated loss of precision

Non-relation domains cannot represent variable **relationships**

## Rate limiter

```

Y ← 0; while ● 1=1 do
  X ← [-128,128]; D ← [0,16];
  S ← Y; Y ← X; R ← X - S;
  if R ≤ -D then Y ← S - D fi;
  if R ≥ D then Y ← S + D fi
done

```

X: input signal  
 Y: output signal  
 S: last output  
 R: delta  $Y - S$   
 D: max. allowed for  $|R|$

# Accumulated loss of precision

Non-relation domains cannot represent variable **relationships**

## Rate limiter

```

Y ← 0; while • 1=1 do
  X ← [-128,128]; D ← [0,16];
  S ← Y; Y ← X; R ← X - S;
  if R ≤ -D then Y ← S - D fi;
  if R ≥ D then Y ← S + D fi
done

```

X: input signal  
 Y: output signal  
 S: last output  
 R: delta  $Y - S$   
 D: max. allowed for  $|R|$

Iterations in the interval domain (without widening):

$\mathcal{X}^{\#0}$	$\mathcal{X}^{\#1}$	$\mathcal{X}^{\#2}$	...	$\mathcal{X}^{\#n}$
$Y = 0$	$ Y  \leq 144$	$ Y  \leq 160$	...	$ Y  \leq 128 + 16n$

In fact,  $Y \in [-128, 128]$  always holds.

To prove that, e.g.  $Y \geq -128$ , we must be able to:

- **represent** the properties  $R = X - S$  and  $R \leq -D$
- **combine** them to deduce  $S - X \geq D$ , and then  $Y = S - D \geq X$

# The need for relational loop invariants

To prove some invariant after the **end of a loop**,  
we often need to find a **loop invariant** of a **more complex form**

relational loop invariant

```
X ← 0; I ← 1;
while • I < 5000 do
  if [0,1] = 1 then X ← X + 1 else X ← X - 1 fi;
  I ← I + 1
done ♦
```

A non-relational analysis finds at ♦ that  $I = 5000$  and  $X \in \mathbb{Z}$

The best invariant is:  $(I = 5000) \wedge (X \in [-4999, 4999]) \wedge (X \equiv 0 [2])$

To find this **non-relational** invariant, we must find a **relational** loop invariant at  
•:  $(-I < X < I) \wedge (X + I \equiv 1 [2]) \wedge (I \in [1, 5000])$ ,  
and apply the loop exit condition  $C^\sharp \llbracket I \geq 5000 \rrbracket$

# Modular analysis

store the maximum of  $X, Y, 0$  into  $Z$

max( $X, Y, Z$ )

```
Z ← X ;
if Y > Z then Z ← Y ;
if Z < 0 then Z ← 0;
```

Modular analysis:

- analyze a function **once** (function summary)
- **reuse** the summary at each call site (instantiation)  
 ⇒ improved efficiency

# Modular analysis

store the maximum of  $X, Y, 0$  into  $Z'$

max( $X, Y, Z$ )

$X' \leftarrow X; Y' \leftarrow Y; Z' \leftarrow Z;$

$Z' \leftarrow X';$

if  $Y' > Z'$  then  $Z' \leftarrow Y';$

if  $Z' < 0$  then  $Z' \leftarrow 0;$

$(Z' \geq X \wedge Z' \geq Y \wedge Z' \geq 0 \wedge X' = X \wedge Y' = Y)$

Modular analysis:

- analyze a function **once** (function summary)
- **reuse** the summary at each call site (instantiation)  
 $\implies$  improved efficiency
- infer a **relation** between input  $X, Y, Z$  and output  $X', Y', Z'$  values, in  $\mathcal{P}((\mathbb{V} \rightarrow \mathbb{R}) \times (\mathbb{V} \rightarrow \mathbb{R})) \simeq \mathcal{P}((\mathbb{V} \times \mathbb{V}) \rightarrow \mathbb{R})$
- requires inferring **relational information** [Anco10], [Jean09]

# Linear equality domain

---

# The affine equality domain

Here  $\mathbb{I} \in \{\mathbb{Q}, \mathbb{R}\}$ .

We look for invariants of the form:

$$\bigwedge_j \left( \sum_{i=1}^n \alpha_{ij} V_i = \beta_j \right), \alpha_{ij}, \beta_j \in \mathbb{I}$$

where all the  $\alpha_{ij}$  and  $\beta_j$  are inferred automatically.

We use a domain of affine spaces proposed by [Karr76]:

$$\mathcal{D}^\# \stackrel{\text{def}}{=} \{ \text{affine subspaces of } \mathbb{V} \rightarrow \mathbb{I} \}$$

# Affine equality representation

Machine representation: an affine subspace is represented as

- either the constant  $\perp^\sharp$ ,
- or a pair  $\langle \mathbf{M}, \vec{C} \rangle$  where
  - $\mathbf{M} \in \mathbb{I}^{m \times n}$  is a  $m \times n$  matrix,  $n = |\mathbb{V}|$  and  $m \leq n$ ,
  - $\vec{C} \in \mathbb{I}^m$  is a row-vector with  $m$  rows.

$\langle \mathbf{M}, \vec{C} \rangle$  represents an equation system, with solutions:

$$\gamma(\langle \mathbf{M}, \vec{C} \rangle) \stackrel{\text{def}}{=} \{ \vec{V} \in \mathbb{I}^n \mid \mathbf{M} \times \vec{V} = \vec{C} \}$$

$\mathbf{M}$  should be in **row echelon form**:

- $\forall i \leq m: \exists k_i: M_{ik_i} = 1$  and  
 $\forall c < k_i: M_{ic} = 0, \forall i \neq i': M_{ik_i} = 0$ ,
- if  $i < i'$  then  $k_i < k_{i'}$  (leading index)

example:

$$\begin{bmatrix} 1 & 0 & 0 & 5 & 0 \\ 0 & 1 & 0 & 6 & 0 \\ 0 & 0 & 1 & 7 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

Remarks:

the representation is unique

as  $m \leq n = |\mathbb{V}|$ , the memory cost is in  $\mathcal{O}(n^2)$  at worst

$\top$  is represented as the empty equation system:  $m = 0$

# Normalisation and emptiness testing

Let  $\mathbf{M} \times \vec{V} = \vec{C}$  be an equation system, not necessarily in normal form.

The **Gaussian reduction** *Gauss*( $\langle \mathbf{M}, \vec{C} \rangle$ ) tells in  $\mathcal{O}(n^3)$  time:

- whether the system is satisfiable, and in that case
- gives an equivalent system  $\langle \mathbf{M}', \vec{C}' \rangle$  in normal form

i.e. returns an element in  $\mathcal{D}^\sharp$ .

Principle: reorder lines, make linear combinations of lines to eliminate variables

Example:

$$\left\{ \begin{array}{rclclcl} 2X & + & Y & + & Z & = & 19 \\ 2X & + & Y & - & Z & = & 9 \\ & & & & 3Z & = & 15 \end{array} \right.$$

$\Downarrow$

$$\left\{ \begin{array}{rclcl} X & + & 0.5Y & & & = & 7 \\ & & & & Z & = & 5 \end{array} \right.$$

# Affine equality operators

## Applications

If  $\mathcal{X}^\#, \mathcal{Y}^\# \neq \perp^\#$ , we define:

$$\mathcal{X}^\# \cap^\# \mathcal{Y}^\# \stackrel{\text{def}}{=} \text{Gauss} \left( \left\langle \begin{bmatrix} \mathbf{M}_{\mathcal{X}^\#} \\ \mathbf{M}_{\mathcal{Y}^\#} \end{bmatrix}, \begin{bmatrix} \vec{c}_{\mathcal{X}^\#} \\ \vec{c}_{\mathcal{Y}^\#} \end{bmatrix} \right\rangle \right)$$

$$\mathcal{X}^\# =^\# \mathcal{Y}^\# \stackrel{\text{def}}{\iff} \mathbf{M}_{\mathcal{X}^\#} = \mathbf{M}_{\mathcal{Y}^\#} \quad \text{and} \quad \vec{c}_{\mathcal{X}^\#} = \vec{c}_{\mathcal{Y}^\#}$$

$$\mathcal{X}^\# \subseteq^\# \mathcal{Y}^\# \stackrel{\text{def}}{\iff} \mathcal{X}^\# \cap^\# \mathcal{Y}^\# =^\# \mathcal{X}^\#$$

$$\mathbf{C}^\# [\sum_j \alpha_j V_j = \beta] \mathcal{X}^\# \stackrel{\text{def}}{=} \text{Gauss} \left( \left\langle \begin{bmatrix} \mathbf{M}_{\mathcal{X}^\#} \\ \alpha_1 \cdots \alpha_n \end{bmatrix}, \begin{bmatrix} \vec{c}_{\mathcal{X}^\#} \\ \beta \end{bmatrix} \right\rangle \right)$$

$$\mathbf{C}^\# [e \bowtie 0] \mathcal{X}^\# \stackrel{\text{def}}{=} \mathcal{X}^\# \quad \text{for other tests}$$

## Remarks:

$\subseteq^\#, =^\#, \cap^\#, =^\#$  and  $\mathbf{C}^\# [\sum_j \alpha_j V_j = \beta]$  are **exact**:

$$\mathcal{X}^\# \subseteq^\# \mathcal{Y}^\# \iff \gamma(\mathcal{X}^\#) \subseteq \gamma(\mathcal{Y}^\#), \quad \gamma(\mathcal{X}^\# \cap^\# \mathcal{Y}^\#) = \gamma(\mathcal{X}^\#) \cap \gamma(\mathcal{Y}^\#), \dots$$

# Generator representation

## Generator representation

An affine subspace can also be represented as a set of **vector generators**  $\vec{G}_1, \dots, \vec{G}_m$  and an **origin point**  $\vec{O}$ , denoted as  $[\mathbf{G}, \vec{O}]$ .

$$\gamma([\mathbf{G}, \vec{O}]) \stackrel{\text{def}}{=} \{ \mathbf{G} \times \vec{\lambda} + \vec{O} \mid \vec{\lambda} \in \mathbb{I}^m \} \quad (\mathbf{G} \in \mathbb{I}^{n \times m}, \vec{O} \in \mathbb{I}^n)$$

We can **switch** between a generator and a constraint representation:

- From generators to constraints:  $\langle \mathbf{M}, \vec{C} \rangle = \text{Cons}([\mathbf{G}, \vec{O}])$

Write the system  $\vec{V} = \mathbf{G} \times \vec{\lambda} + \vec{O}$  with variables  $\vec{V}, \vec{\lambda}$ .

Solve it in  $\vec{\lambda}$  (by row operations).

Keep the constraints involving only  $\vec{V}$ .

$$\text{e.g. } \begin{cases} X &= \lambda + 2 \\ Y &= 2\lambda + \mu + 3 \\ Z &= \mu \end{cases} \implies \begin{cases} X - 2 &= \lambda \\ -2X + Y + 1 &= \mu \\ 2X - Y + Z - 1 &= 0 \end{cases}$$

The result is:  $2X - Y + Z = 1$ .

# Generator representation (cont.)

- From constraints to generators:  $[\mathbf{G}, \vec{O}] \stackrel{\text{def}}{=} \text{Gen}(\langle \mathbf{M}, \vec{C} \rangle)$

Assume  $\langle \mathbf{M}, \vec{C} \rangle$  is normalized.

For each non-leading variable  $V$ , assign a distinct  $\lambda_V$ ,  
solve leading variables in terms of non-leading ones.

$$\text{e.g. } \begin{cases} X + 0.5Y &= 7 \\ Z &= 5 \end{cases} \implies \begin{bmatrix} -0.5 \\ 1 \\ 0 \end{bmatrix} \lambda_Y + \begin{bmatrix} 7 \\ 0 \\ 5 \end{bmatrix}$$

# Affine equality operators (cont.)

## Applications

Given  $\mathcal{X}^\sharp, \mathcal{Y}^\sharp \neq \perp^\sharp$ , we define:

$$\mathcal{X}^\sharp \cup^\sharp \mathcal{Y}^\sharp \stackrel{\text{def}}{=} \text{Cons} \left( \left[ \mathbf{G}_{\mathcal{X}^\sharp} \mathbf{G}_{\mathcal{Y}^\sharp} (\vec{O}_{\mathcal{Y}^\sharp} - \vec{O}_{\mathcal{X}^\sharp}), \vec{O}_{\mathcal{X}^\sharp} \right] \right)$$

$$\mathbf{C}^\sharp \llbracket V_j \leftarrow [-\infty, +\infty] \rrbracket \mathcal{X}^\sharp \stackrel{\text{def}}{=} \text{Cons} \left( \left[ \mathbf{G}_{\mathcal{X}^\sharp} \vec{x}_j, \vec{O}_{\mathcal{X}^\sharp} \right] \right)$$

$$\mathbf{C}^\sharp \llbracket V_j \leftarrow \sum_i \alpha_i V_i + \beta \rrbracket \mathcal{X}^\sharp \stackrel{\text{def}}{=}$$

if  $\alpha_j = 0$ ,  $(\mathbf{C}^\sharp \llbracket V_j = \sum_i \alpha_i V_i + \beta \rrbracket \circ \mathbf{C}^\sharp \llbracket V_j \leftarrow [-\infty, +\infty] \rrbracket) \mathcal{X}^\sharp$

if  $\alpha_j \neq 0$ ,  $\mathcal{X}^\sharp$  where  $V_j$  is replaced with  $(V_j - \sum_{i \neq j} \alpha_i V_i - \beta) / \alpha_j$

(proofs on next slide)

$$\mathbf{C}^\sharp \llbracket V_j \leftarrow e \rrbracket \mathcal{X}^\sharp \stackrel{\text{def}}{=} \mathbf{C}^\sharp \llbracket V_j \leftarrow [-\infty, +\infty] \rrbracket \mathcal{X}^\sharp \text{ for other assignments}$$

## Remarks:

- $\cup^\sharp$  is **optimal**, but not exact.
- $\mathbf{C}^\sharp \llbracket V_j \leftarrow \sum_i \alpha_i V_i + \beta \rrbracket$  and  $\mathbf{C}^\sharp \llbracket V_j \leftarrow [-\infty, +\infty] \rrbracket$  are **exact**.

# Affine assignments: proofs

$$\mathcal{C}^\sharp \llbracket V_j \leftarrow \sum_i \alpha_i V_i + \beta \rrbracket \mathcal{X}^\sharp \stackrel{\text{def}}{=}$$

if  $\alpha_j = 0$ ,  $(\mathcal{C}^\sharp \llbracket V_j = \sum_i \alpha_i V_i + \beta \rrbracket \circ \mathcal{C}^\sharp \llbracket V_j \leftarrow [-\infty, +\infty] \rrbracket) \mathcal{X}^\sharp$

if  $\alpha_j \neq 0$ ,  $\mathcal{X}^\sharp$  where  $V_j$  is replaced with  $(V_j - \sum_{i \neq j} \alpha_i V_i - \beta) / \alpha_j$

Proof sketch:

we use the following identities in the concrete

- **non-invertible** assignment:  $\alpha_j = 0$

$\mathcal{C} \llbracket V_j \leftarrow e \rrbracket = \mathcal{C} \llbracket V_j \leftarrow e \rrbracket \circ \mathcal{C} \llbracket V_j \leftarrow [-\infty, +\infty] \rrbracket$  as the value of  $V_j$  is not used in  $e$   
 so:  $\mathcal{C} \llbracket V_j \leftarrow e \rrbracket = \mathcal{C} \llbracket V_j = e \rrbracket \circ \mathcal{C} \llbracket V_j \leftarrow [-\infty, +\infty] \rrbracket$

$\implies$  reduces the assignment to a test

- **invertible** assignment:  $\alpha_j \neq 0$

$\mathcal{C} \llbracket V_j \leftarrow e \rrbracket \subsetneq \mathcal{C} \llbracket V_j \leftarrow e \rrbracket \circ \mathcal{C} \llbracket V_j \leftarrow [-\infty, +\infty] \rrbracket$  as  $e$  depends on  $V$

(e.g.,  $\mathcal{C} \llbracket V \leftarrow V + 1 \rrbracket \neq \mathcal{C} \llbracket V \leftarrow V + 1 \rrbracket \circ \mathcal{C} \llbracket V \leftarrow [-\infty, +\infty] \rrbracket$ )

$$\begin{aligned} \rho \in \mathcal{C} \llbracket V_j \leftarrow e \rrbracket R &\iff \exists \rho' \in R: \rho = \rho'[V_j \mapsto \sum_i \alpha_i \rho'(V_i) + \beta] \\ &\iff \exists \rho' \in R: \rho[V_j \mapsto (\rho(V_j) - \sum_{i \neq j} \alpha_i \rho'(V_i) - \beta) / \alpha_j] = \rho' \\ &\iff \rho[V_j \mapsto (\rho(V_j) - \sum_{i \neq j} \alpha_i \rho(V_i) - \beta) / \alpha_j] \in R \end{aligned}$$

$\implies$  reduces the assignment to a substitution by the inverse expression

# Analysis example

No infinite increasing chain: we can iterate without widening.

## Forward analysis example:

```

1X ← 10; Y ← 100;
while 2X ≠ 0 do 3
  X ← X-1;
  Y ← Y+10
done 4

```

$\ell$	$\mathcal{X}_\ell^{\#0}$	$\mathcal{X}_\ell^{\#1}$	$\mathcal{X}_\ell^{\#2}$	$\mathcal{X}_\ell^{\#3}$	$\mathcal{X}_\ell^{\#4}$
1	$\top^\#$	$\top^\#$	$\top^\#$	$\top^\#$	$\top^\#$
2	$\perp^\#$	(10, 100)	(10, 100)	$10X + Y = 200$	$10X + Y = 200$
3	$\perp^\#$	$\perp^\#$	(10, 100)	(10, 100)	$10X + Y = 200$
4	$\perp^\#$	$\perp^\#$	$\perp^\#$	$\perp^\#$	(0, 200)

Note in particular:

$$\mathcal{X}_2^{\#3} = \{(10, 100)\} \cup^\# \{(9, 110)\} = \{(X, Y) \mid 10X + Y = 200\}$$

# Polyhedron domain

---

# The polyhedron domain

Here again  $\mathbb{I} \in \{\mathbb{Q}, \mathbb{R}\}$ .

We look for invariants of the form:  $\bigwedge_j \left( \sum_{i=1}^n \alpha_{ij} V_i \geq \beta_j \right)$ .

We use the polyhedron domain proposed by [Cous78]:

$$\mathcal{D}^\# \stackrel{\text{def}}{=} \{\text{closed convex polyhedra of } \mathbb{V} \rightarrow \mathbb{I}\}$$

Note: polyhedra need not be bounded ( $\neq$  polytopes).

# Double description of polyhedra

Polyhedra have **dual** representations (Weyl–Minkowski Theorem).

(see [Schr86])

## Constraint representation

$\langle \mathbf{M}, \vec{C} \rangle$  with  $\mathbf{M} \in \mathbb{I}^{m \times n}$  and  $\vec{C} \in \mathbb{I}^m$  represents:

$$\gamma(\langle \mathbf{M}, \vec{C} \rangle) \stackrel{\text{def}}{=} \{ \vec{V} \mid \mathbf{M} \times \vec{V} \geq \vec{C} \}$$

We will also often use a **constraint set notation**  $\{ \sum_i \alpha_{ij} V_i \geq \beta_j \}$ .

## Generator representation

$[\mathbf{P}, \mathbf{R}]$  where:

- $\mathbf{P} \in \mathbb{I}^{n \times p}$  is a set of  $p$  **points**:  $\vec{P}_1, \dots, \vec{P}_p$ ,
- $\mathbf{R} \in \mathbb{I}^{n \times r}$  is a set of  $r$  **rays**:  $\vec{R}_1, \dots, \vec{R}_r$ .

$$\gamma([\mathbf{P}, \mathbf{R}]) \stackrel{\text{def}}{=} \left\{ \left( \sum_{j=1}^p \alpha_j \vec{P}_j \right) + \left( \sum_{j=1}^r \beta_j \vec{R}_j \right) \mid \forall j: \alpha_j \geq 0, \sum_{j=1}^p \alpha_j = 1, \forall j: \beta_j \geq 0 \right\}$$

# Double description of polyhedra (cont.)

## Generator representation examples:

$$\gamma([\mathbf{P}, \mathbf{R}]) \stackrel{\text{def}}{=} \{ (\sum_{j=1}^p \alpha_j \vec{P}_j) + (\sum_{j=1}^r \beta_j \vec{R}_j) \mid \forall j: \alpha_j \geq 0, \sum_{j=1}^p \alpha_j = 1, \forall j: \beta_j \geq 0 \}$$

- the points can only define a bounded convex hull,
- the rays allow unbounded polyhedra.

# Origin of duality

Dual:  $A^* \stackrel{\text{def}}{=} \{ \vec{x} \in \mathbb{I}^n \mid \forall \vec{a} \in A: \vec{a} \cdot \vec{x} \leq 0 \}$

- $\{\vec{a}\}^*$  and  $\{\lambda \vec{r} \mid \lambda \geq 0\}^*$  are half-spaces,
- $(A \cup B)^* = A^* \cap B^*$ ,
- bidual: if  $A$  is convex, closed, and  $\vec{0} \in A$ , then  $A^{**} = A$ .

Duality on polyhedral cones:

Cone:  $C = \{ \vec{V} \mid \mathbf{M} \times \vec{V} \geq \vec{0} \}$  or  $C = \{ \sum_{j=1}^r \beta_j \vec{R}_j \mid \forall j: \beta_j \geq 0 \}$

(polyhedron with no vertex, except  $\vec{0}$ )

- $C^*$  is also a polyhedral cone,
- $C^{**} = C$ ,
- a ray of  $C$  corresponds to a constraint of  $C^*$ ,
- a constraint of  $C$  corresponds to a ray of  $C^*$ .

Extension to polyhedra: by homogenisation to polyhedral cones:

$C(P) \stackrel{\text{def}}{=} \{ \lambda \vec{V} \mid \lambda \geq 0, (V_1, \dots, V_n) \in \gamma(P), V_{n+1} = 1 \} \subseteq \mathbb{I}^{n+1}$

(polyhedron in  $\mathbb{I}^n \simeq$  polyhedral cone in  $\mathbb{I}^{n+1}$ )

# Polyhedra representations

- **no best abstraction**  $\alpha$ ,  
(e.g., a disc has infinitely many polyhedral over-approximations, but no best one)
- **no memory bound** on the representations.

# Polyhedra representations

## Minimal representations

- A constraint / generator system is **minimal** if no constraint / generator can be omitted without changing the concretization.
- Minimal representations are **not unique**.
- No memory bound even on minimal representations.

Example: three different constraint representations for a point

(a)

(b)

(c)

- (a)  $y + x \geq 0, y - x \geq 0, y \leq 0, y \geq -5$
- (b)  $y + x \geq 0, y - x \geq 0, y \leq 0$
- (c)  $x \leq 0, x \geq 0, y \leq 0, y \geq 0$

(non minimal)

(minimal)

(minimal)

# Chernikova's algorithm

Algorithm by [Cher68], improved by [LeVe92] to switch from a constraint system to an equivalent generator system.

Why? most operators are easier on one representation.

## Notes:

- By **duality**, we can use the same algorithm to switch from generators to constraints.
- The minimal generator system can be **exponential** in the original constraint system. (e.g., hypercube:  $2n$  constraints,  $2^n$  vertices)
- **Equality** constraints and **lines** (pairs of opposed rays) may be handled separately and more efficiently.

# Chernikova's algorithm (cont.)

**Algorithm:** incrementally add constraints one by one

Start with: 
$$\begin{cases} \mathbf{P}_0 = \{ (0, \dots, 0) \} & \text{(origin)} \\ \mathbf{R}_0 = \{ \vec{x}_i, -\vec{x}_i \mid 1 \leq i \leq n \} & \text{(axes)} \end{cases}$$

For each constraint  $\vec{M}_k \cdot \vec{V} \geq C_k \in \langle \mathbf{M}, \vec{C} \rangle$ , update  $[\mathbf{P}_{k-1}, \mathbf{R}_{k-1}]$  to  $[\mathbf{P}_k, \mathbf{R}_k]$ .

Start with  $\mathbf{P}_k = \mathbf{R}_k = \emptyset$ ,

- for any  $\vec{P} \in \mathbf{P}_{k-1}$  s.t.  $\vec{M}_k \cdot \vec{P} \geq C_k$ , add  $\vec{P}$  to  $\mathbf{P}_k$
- for any  $\vec{R} \in \mathbf{R}_{k-1}$  s.t.  $\vec{M}_k \cdot \vec{R} \geq 0$ , add  $\vec{R}$  to  $\mathbf{R}_k$
- for any  $\vec{P}, \vec{Q} \in \mathbf{P}_{k-1}$  s.t.  $\vec{M}_k \cdot \vec{P} > C_k$  and  $\vec{M}_k \cdot \vec{Q} < C_k$ , add to  $\mathbf{P}_k$ :

$$\vec{O} \stackrel{\text{def}}{=} \frac{C_k - \vec{M}_k \cdot \vec{Q}}{\vec{M}_k \cdot \vec{P} - \vec{M}_k \cdot \vec{Q}} \vec{P} - \frac{C_k - \vec{M}_k \cdot \vec{P}}{\vec{M}_k \cdot \vec{P} - \vec{M}_k \cdot \vec{Q}} \vec{Q}$$

i.e., move  $Q$  towards  $P$  along  $[Q, P]$  until it saturates the constraint

# Chernikova's algorithm (cont.)

- for any  $\vec{R}, \vec{S} \in \mathbf{R}_{k-1}$  s.t.  $\vec{M}_k \cdot \vec{R} > 0$  and  $\vec{M}_k \cdot \vec{S} < 0$ , add to  $\mathbf{R}_k$ :

$$\vec{O} \stackrel{\text{def}}{=} (\vec{M}_k \cdot \vec{S})\vec{R} - (\vec{M}_k \cdot \vec{R})\vec{S}$$

i.e., rotate  $S$  towards  $R$  until it is parallel to the constraint

- for any  $\vec{P} \in \mathbf{P}_{k-1}, \vec{R} \in \mathbf{R}_{k-1}$  s.t.  
either  $\vec{M}_k \cdot \vec{P} > C_k$  and  $\vec{M}_k \cdot \vec{R} < 0$ , or  $\vec{M}_k \cdot \vec{P} < C_k$  and  $\vec{M}_k \cdot \vec{R} > 0$   
add to  $\mathbf{P}_k$ :  $\vec{O} \stackrel{\text{def}}{=} \vec{P} + \frac{C_k - \vec{M}_k \cdot \vec{P}}{\vec{M}_k \cdot \vec{R}} \vec{R}$

# Chernikova's algorithm example

## Example:

$$\mathbf{P}_0 = \{(0, 0)\}$$

$$\mathbf{R}_0 = \{(1, 0), (-1, 0), (0, 1), (0, -1)\}$$

# Chernikova's algorithm example

## Example:

$$Y \geq 1$$

$$\mathbf{P}_0 = \{(0, 0)\}$$

$$\mathbf{P}_1 = \{(0, 1)\}$$

$$\mathbf{R}_0 = \{(1, 0), (-1, 0), (0, 1), (0, -1)\}$$

$$\mathbf{R}_1 = \{(1, 0), (-1, 0), (0, 1)\}$$

# Chernikova's algorithm example

## Example:

$$\begin{aligned}
 Y &\geq 1 \\
 X + Y &\geq 3
 \end{aligned}$$

$$P_0 = \{(0, 0)\}$$

$$P_1 = \{(0, 1)\}$$

$$P_2 = \{(2, 1)\}$$

$$R_0 = \{(1, 0), (-1, 0), (0, 1), (0, -1)\}$$

$$R_1 = \{(1, 0), (-1, 0), (0, 1)\}$$

$$R_2 = \{(1, 0), (-1, 1), (0, 1)\}$$

# Chernikova's algorithm example

## Example:

	$P_0 = \{(0, 0)\}$	$R_0 = \{(1, 0), (-1, 0), (0, 1), (0, -1)\}$
$Y \geq 1$	$P_1 = \{(0, 1)\}$	$R_1 = \{(1, 0), (-1, 0), (0, 1)\}$
$X + Y \geq 3$	$P_2 = \{(2, 1)\}$	$R_2 = \{(1, 0), (-1, 1), (0, 1)\}$
$X - Y \leq 1$	$P_3 = \{(2, 1), (1, 2)\}$	$R_3 = \{(0, 1), (1, 1)\}$

# Redundancy removal

**Goal:** introduce only non-redundant generators during Chernikova's algorithm.

Definitions (for rays in polyhedral cones)

Given  $C = \{ \vec{V} \mid \mathbf{M} \times \vec{V} \geq \vec{0} \} = \{ \mathbf{R} \times \vec{\beta} \mid \vec{\beta} \geq \vec{0} \}$ .

$$\blacksquare \vec{R} \text{ saturates } \vec{M}_k \cdot \vec{V} \geq 0 \stackrel{\text{def}}{\iff} \vec{M}_k \cdot \vec{R} = 0.$$

$$\blacksquare S(\vec{R}, C) \stackrel{\text{def}}{=} \{ k \mid \vec{M}_k \cdot \vec{R} = 0 \}.$$

Theorem:

Assume  $C$  has no line ( $\nexists \vec{L} \neq \vec{0}$  s.t.  $\forall \alpha: \alpha \vec{L} \in C$ ),  
then  $\vec{R}$  is non-redundant w.r.t.  $\mathbf{R} \iff \nexists \vec{R}_i \in \mathbf{R}: S(\vec{R}, C) \subseteq S(\vec{R}_i, C)$ .

- $S(\vec{R}_i, C)$ ,  $\vec{R}_i \in \mathbf{R}$  is maintained during Chernikova's algorithm in a saturation matrix,
- extension to (non-conic) polyhedra and to lines,
- various improvements exist [LeVe92].

# Operators on polyhedra

Given  $\mathcal{X}^\#, \mathcal{Y}^\# \neq \perp^\#$ , we define:

$$\mathcal{X}^\# \subseteq^\# \mathcal{Y}^\# \stackrel{\text{def}}{\iff} \begin{cases} \forall \vec{P} \in \mathbf{P}_{\mathcal{X}^\#} : \mathbf{M}_{\mathcal{Y}^\#} \times \vec{P} \geq \vec{C}_{\mathcal{Y}^\#} \\ \forall \vec{R} \in \mathbf{R}_{\mathcal{X}^\#} : \mathbf{M}_{\mathcal{Y}^\#} \times \vec{R} \geq \vec{0} \end{cases}$$

(every generator of  $\mathcal{X}^\#$  must satisfy every constraint in  $\mathcal{Y}^\#$ )

$$\mathcal{X}^\# =^\# \mathcal{Y}^\# \stackrel{\text{def}}{\iff} \mathcal{X}^\# \subseteq^\# \mathcal{Y}^\# \quad \text{and} \quad \mathcal{Y}^\# \subseteq^\# \mathcal{X}^\#$$

$$\mathcal{X}^\# \cap^\# \mathcal{Y}^\# \stackrel{\text{def}}{=} \left\langle \begin{bmatrix} \mathbf{M}_{\mathcal{X}^\#} \\ \mathbf{M}_{\mathcal{Y}^\#} \end{bmatrix}, \begin{bmatrix} \vec{C}_{\mathcal{X}^\#} \\ \vec{C}_{\mathcal{Y}^\#} \end{bmatrix} \right\rangle$$

(set union of sets of constraints)

## Remarks:

- $\subseteq^\#$ ,  $=^\#$  and  $\cap^\#$  are **exact**.

# Operators on polyhedra: join

Join:  $\mathcal{X}^\# \cup^\# \mathcal{Y}^\# \stackrel{\text{def}}{=} [[\mathbf{P}_{\mathcal{X}^\#} \ \mathbf{P}_{\mathcal{Y}^\#}], [\mathbf{R}_{\mathcal{X}^\#} \ \mathbf{R}_{\mathcal{Y}^\#}]]$  (join generator sets)

Examples:

two polytopes

a point and a line

$\cup^\#$  is **optimal**:

we get the **topological closure of the convex hull** of  $\gamma(\mathcal{X}^\#) \cup \gamma(\mathcal{Y}^\#)$ .

# Operators on polyhedra: tests

Forward operators: affine tests

$$C^\sharp[\sum_i \alpha_i V_i + \beta \geq 0] \mathcal{X}^\sharp \stackrel{\text{def}}{=} \left\langle \begin{bmatrix} \mathbf{M}_{\mathcal{X}^\sharp} \\ \alpha_1 \cdots \alpha_n \end{bmatrix}, \begin{bmatrix} \vec{C}_{\mathcal{X}^\sharp} \\ -\beta \end{bmatrix} \right\rangle$$

$$C^\sharp[\sum_i \alpha_i V_i = \beta] \mathcal{X}^\sharp \stackrel{\text{def}}{=} (C^\sharp[\sum_i \alpha_i V_i \geq \beta] \circ C^\sharp[\sum_i \alpha_i V_i \leq \beta]) \mathcal{X}^\sharp$$

These test operators are exact.

# Operators on polyhedra: non-deterministic assignment

Forward operators: forget

$$C^\sharp \llbracket V_j \leftarrow [-\infty, +\infty] \rrbracket \mathcal{X}^\sharp \stackrel{\text{def}}{=} [P_{\mathcal{X}^\sharp}, [R_{\mathcal{X}^\sharp} \vec{x}_j \ (-\vec{x}_j)]]$$

This operator is exact.

It is also a sound abstraction for any assignment.

# Operators on polyhedra: affine assignments

Forward operators: affine assignments

$$\mathcal{C}^\sharp \llbracket V_j \leftarrow \sum_i \alpha_i V_i + \beta \rrbracket \mathcal{X}^\sharp \stackrel{\text{def}}{=}$$

if  $\alpha_j = 0$ ,  $(\mathcal{C}^\sharp \llbracket V_j = \sum_i \alpha_i V_i + \beta \rrbracket \circ \mathcal{C}^\sharp \llbracket V_j \leftarrow [-\infty, +\infty] \rrbracket) \mathcal{X}^\sharp$

if  $\alpha_j \neq 0$ ,  $\langle \mathbf{M}, \vec{C} \rangle$  where  $V_j$  is replaced with  $\frac{1}{\alpha_j}(V_j - \sum_{i \neq j} \alpha_i V_i - \beta)$

Examples :

$$X \leftarrow X + Y$$

$$X \leftarrow Y$$

Affine assignments are exact.

They could also be defined on generator systems.

# Affine assignments: proofs

$$\mathcal{C}^\# \llbracket V_j \leftarrow \sum_i \alpha_i V_i + \beta \rrbracket \mathcal{X}^\# \stackrel{\text{def}}{=} \mathcal{X}^\#$$

if  $\alpha_j = 0$ ,  $(\mathcal{C}^\# \llbracket \sum_i \alpha_i V_i - V_j + \beta = 0 \rrbracket \circ \mathcal{C}^\# \llbracket V_j \leftarrow [-\infty, +\infty] \rrbracket) \mathcal{X}^\#$

if  $\alpha_j \neq 0$ ,  $\mathcal{X}^\#$  where  $V_j$  is replaced with  $(V_j - \sum_{i \neq j} \alpha_i V_i - \beta) / \alpha_j$

Proof sketch:

we use the following identities in the concrete

**non-invertible** assignment:  $\alpha_j = 0$

$\mathcal{C} \llbracket V_j \leftarrow e \rrbracket = \mathcal{C} \llbracket V_j \leftarrow e \rrbracket \circ \mathcal{C} \llbracket V_j \leftarrow [-\infty, +\infty] \rrbracket$  as the value of  $V_j$  is not used in  $e$   
 so:  $\mathcal{C} \llbracket V_j \leftarrow e \rrbracket = \mathcal{C} \llbracket V_j = e \rrbracket \circ \mathcal{C} \llbracket V_j \leftarrow [-\infty, +\infty] \rrbracket$

$\implies$  reduces the assignment to a test

**invertible** assignment:  $\alpha_j \neq 0$

$\mathcal{C} \llbracket V_j \leftarrow e \rrbracket \subsetneq \mathcal{C} \llbracket V_j \leftarrow e \rrbracket \circ \mathcal{C} \llbracket V_j \leftarrow [-\infty, +\infty] \rrbracket$  as  $e$  depends on  $V$   
 (e.g.,  $\mathcal{C} \llbracket V \leftarrow V + 1 \rrbracket \neq \mathcal{C} \llbracket V \leftarrow V + 1 \rrbracket \circ \mathcal{C} \llbracket V \leftarrow [-\infty, +\infty] \rrbracket$ )

$$\begin{aligned} \rho \in \mathcal{C} \llbracket V_j \leftarrow e \rrbracket R &\iff \exists \rho' \in R: \rho = \rho' [V_j \mapsto \sum_i \alpha_i \rho'(V_i) + \beta] \\ &\iff \exists \rho' \in R: \rho[V_j \mapsto (\rho(V_j) - \sum_{i \neq j} \alpha_i \rho'(V_i) - \beta) / \alpha_j] = \rho' \\ &\iff \rho[V_j \mapsto (\rho(V_j) - \sum_{i \neq j} \alpha_i \rho(V_i) - \beta) / \alpha_j] \in R \end{aligned}$$

$\implies$  reduces the assignment to a substitution by the inverse expression

# Operators on polyhedra: backward assignments

## Backward assignments:

$$\overleftarrow{C}^\# \llbracket V_j \leftarrow [-\infty, +\infty] \rrbracket (\mathcal{X}^\#, \mathcal{R}^\#) \stackrel{\text{def}}{=} \mathcal{X}^\# \cap^\# (C^\# \llbracket V_j \leftarrow [-\infty, +\infty] \rrbracket \mathcal{R}^\#)$$

$$\overleftarrow{C}^\# \llbracket V_j \leftarrow \sum_i \alpha_i V_i + \beta \rrbracket (\mathcal{X}^\#, \mathcal{R}^\#) \stackrel{\text{def}}{=} \mathcal{X}^\# \cap^\# (\mathcal{R}^\# \text{ where } V_j \text{ is replaced with } (\sum_i \alpha_i V_i + \beta))$$

$$\overleftarrow{C}^\# \llbracket V_j \leftarrow e \rrbracket (\mathcal{X}^\#, \mathcal{R}^\#) \stackrel{\text{def}}{=} \overleftarrow{C}^\# \llbracket V_j \leftarrow [-\infty, +\infty] \rrbracket (\mathcal{X}^\#, \mathcal{R}^\#)$$

for other assignments

Note: identical to the case of linear equalities.

# Polyhedra widening

$\mathcal{D}^\#$  has strictly increasing infinite chains  $\implies$  we need a widening.

## Definition:

Take  $\mathcal{X}^\#$  and  $\mathcal{Y}^\#$  in minimal constraint-set form, then

$$\mathcal{X}^\# \nabla \mathcal{Y}^\# \stackrel{\text{def}}{=} \{c \in \mathcal{X}^\# \mid \mathcal{Y}^\# \subseteq^\# \{c\}\}$$

We suppress any unstable constraint  $c \in \mathcal{X}^\#$ , i.e.,  $\mathcal{Y}^\# \not\subseteq^\# \{c\}$ .

## Example:

# Polyhedra widening

$\mathcal{D}^\#$  has strictly increasing infinite chains  $\implies$  we need a widening.

## Definition:

Take  $\mathcal{X}^\#$  and  $\mathcal{Y}^\#$  in minimal constraint-set form, then

$$\mathcal{X}^\# \nabla \mathcal{Y}^\# \stackrel{\text{def}}{=} \begin{aligned} & \{c \in \mathcal{X}^\# \mid \mathcal{Y}^\# \subseteq^\# \{c\}\} \\ \cup & \{c \in \mathcal{Y}^\# \mid \exists c' \in \mathcal{X}^\# : \mathcal{X}^\# =^\# (\mathcal{X}^\# \setminus c') \cup \{c\}\} \end{aligned}$$

We suppress any unstable constraint  $c \in \mathcal{X}^\#$ , i.e.,  $\mathcal{Y}^\# \not\subseteq^\# \{c\}$ .

We also keep constraints  $c \in \mathcal{Y}^\#$  equivalent to those in  $\mathcal{X}^\#$ , i.e., when  $\exists c' \in \mathcal{X}^\# : \mathcal{X}^\# =^\# (\mathcal{X}^\# \setminus c') \cup \{c\}$ .

## Example:

# Example analysis

```

X ← 2; I ← 0;
while • I < 10 do
  if [0,1] = 0 then X ← X + 2 else X ← X - 3 fi;
  I ← I + 1
done ♦

```

Loop invariant:

Increasing iterations with widening at • give:

$$\begin{aligned}
 \mathcal{X}_1^\# &= \{X = 2, I = 0\} \\
 \mathcal{X}_2^\# &= \{X = 2, I = 0\} \nabla (\{X = 2, I = 0\} \cup^\# \{X \in [-1, 4], I = 1\}) \\
 &= \{X = 2, I = 0\} \nabla \{I \in [0, 1], 2 - 3I \leq X \leq 2I + 2\} \\
 &= \{I \geq 0, 2 - 3I \leq X \leq 2I + 2\}
 \end{aligned}$$

Decreasing iterations (to find  $I \leq 10$ ):

$$\begin{aligned}
 \mathcal{X}_3^\# &= \{X = 2, I = 0\} \cup^\# \{I \in [1, 10], 2 - 3I \leq X \leq 2I + 2\} \\
 &= \{I \in [0, 10], 2 - 3I \leq X \leq 2I + 2\}
 \end{aligned}$$

We find, at the end of the loop ♦:  $I = 10 \wedge X \in [-28, 22]$ .

# Other polyhedra widenings

## Widening with thresholds:

Given a **finite** set  $T$  of **constraints**, we add to  $\mathcal{X}^\# \nabla \mathcal{Y}^\#$  all the constraints from  $T$  satisfied by both  $\mathcal{X}^\#$  and  $\mathcal{Y}^\#$ .

## Delayed widening:

We replace  $\mathcal{X}^\# \nabla \mathcal{Y}^\#$  with  $\mathcal{X}^\# \cup^\# \mathcal{Y}^\#$  a **finite** number of times.  
(this works for any widening and abstract domain).

See also [Bagn03].

# Integer polyhedra

How can we deal with  $\mathbb{I} = \mathbb{Z}$ ?

**Issue:** integer linear programming is difficult.

Example: satisfiability of conjunctions of linear constraints:

- polynomial cost in  $\mathbb{Q}$ ,
- NP-complete cost in  $\mathbb{Z}$ .

## Possible solutions:

- Use some complete integer algorithms.  
(e.g. Presburger arithmetic)  
Costly, and we do not have any abstract domain structure.
- Keep  $\mathbb{Q}$ -polyhedra as representation, and change the concretization into:  

$$\gamma_{\mathbb{Z}}(\mathcal{X}^{\#}) \stackrel{\text{def}}{=} \gamma(\mathcal{X}^{\#}) \cap \mathbb{Z}^n.$$
 However, operators are no longer exact / optimal.

# Weakly relational domains

---

# Zone domain

---

# The zone domain

Here,  $\mathbb{I} \in \{\mathbb{Z}, \mathbb{Q}, \mathbb{R}\}$ .

We look for invariants of the form:

$$\bigwedge V_i - V_j \leq c \text{ or } \pm V_i \leq c, \quad c \in \mathbb{I}.$$

A subset of  $\mathbb{I}^n$  bounded by such constraints is called a **zone**.

[Miné01a]

# Machine representation

A **potential constraint** has the form:  $V_j - V_i \leq c$ .

**Potential graph:** directed, weighted graph  $\mathcal{G}$

- nodes are labelled with variables in  $\mathbb{V}$ ,
- we add an arc with **weight**  $c$  from  $V_i$  to  $V_j$  for each constraint  $V_j - V_i \leq c$ .

**Difference Bound Matrix** (DBM)

Adjacency matrix  $\mathbf{m}$  of  $\mathcal{G}$ :

- $\mathbf{m}$  is square, with size  $n \times n$ , and elements in  $\mathbb{I} \cup \{+\infty\}$ ,
- $m_{ij} = c < +\infty$  denotes the constraint  $V_j - V_i \leq c$ ,
- $m_{ij} = +\infty$  if there is no upper bound on  $V_j - V_i$ .

**Concretization:**

$$\gamma(\mathbf{m}) \stackrel{\text{def}}{=} \{ (v_1, \dots, v_n) \in \mathbb{I}^n \mid \forall i, j: v_j - v_i \leq m_{ij} \}.$$

# Machine representation (cont.)

**Modeling unary constraints:** add a constant null variable  $V_0$ .

- $\mathbf{m}$  has size  $(n + 1) \times (n + 1)$ ,
- $V_i \leq c$  is denoted as  $V_i - V_0 \leq c$ , i.e.,  $m_{i0} = c$ ,
- $V_i \geq c$  is denoted as  $V_0 - V_i \leq -c$ , i.e.,  $m_{0i} = -c$ ,
- $\gamma$  is now:  $\gamma_0(\mathbf{m}) \stackrel{\text{def}}{=} \{ (v_1, \dots, v_n) \mid (0, v_1, \dots, v_n) \in \gamma(\mathbf{m}) \}$ .

## Example:

	$V_0$	$V_1$	$V_2$
$V_0$	$+\infty$	4	3
$V_1$	-1	$+\infty$	$+\infty$
$V_2$	-1	1	$+\infty$

# The DBM lattice

$\mathcal{D}^\#$  contains all DBMs, plus  $\perp^\#$ .

$\leq$  on  $\mathbb{I} \cup \{+\infty\}$  is extended **point-wisely**.

If  $\mathbf{m}, \mathbf{n} \neq \perp^\#$ :

$$\begin{array}{lll}
 \mathbf{m} \subseteq^\# \mathbf{n} & \stackrel{\text{def}}{\iff} & \forall i, j: m_{ij} \leq n_{ij} \\
 \mathbf{m} =^\# \mathbf{n} & \stackrel{\text{def}}{\iff} & \forall i, j: m_{ij} = n_{ij} \\
 [\mathbf{m} \cap^\# \mathbf{n}]_{ij} & \stackrel{\text{def}}{=} & \min(m_{ij}, n_{ij}) \\
 [\mathbf{m} \cup^\# \mathbf{n}]_{ij} & \stackrel{\text{def}}{=} & \max(m_{ij}, n_{ij}) \\
 [\top^\#]_{ij} & \stackrel{\text{def}}{=} & +\infty
 \end{array}$$

$(\mathcal{D}^\#, \subseteq^\#, \cup^\#, \cap^\#, \perp^\#, \top^\#)$  is a **lattice**.

## Remarks:

- $\mathcal{D}^\#$  is complete if  $\leq$  is ( $\mathbb{I} = \mathbb{R}$  or  $\mathbb{Z}$ , but not  $\mathbb{Q}$ ),
- $\mathbf{m} \subseteq^\# \mathbf{n} \implies \gamma_0(\mathbf{m}) \subseteq \gamma_0(\mathbf{n})$ , but **not the converse**,
- $\mathbf{m} =^\# \mathbf{n} \implies \gamma_0(\mathbf{m}) = \gamma_0(\mathbf{n})$ , but **not the converse**.

# Normal form, equality and inclusion testing

**Issue:** how can we compare  $\gamma_0(\mathbf{m})$  and  $\gamma_0(\mathbf{n})$  precisely?

**Idea:** find a normal form by **propagating/tightening constraints**.

**Definition:** shortest-path closure  $\mathbf{m}^*$

$$m_{ij}^* \stackrel{\text{def}}{=} \min_N \sum_{k=1}^{N-1} m_{i_k i_{k+1}} \\ \langle i = i_1, \dots, i_N = j \rangle$$

Exists only when  $\mathbf{m}$  has no cycle with strictly negative weight.

# Floyd–Warshall algorithm

## Properties:

- $\gamma_0(\mathbf{m}) = \emptyset \iff \mathcal{G}$  has a cycle with strictly negative weight.
- if  $\gamma_0(\mathbf{m}) \neq \emptyset$ , the shortest-path graph  $\mathbf{m}^*$  is a normal form:
 
$$\mathbf{m}^* = \min_{\subseteq^\#} \{ \mathbf{n} \mid \gamma_0(\mathbf{m}) = \gamma_0(\mathbf{n}) \}$$
- If  $\gamma_0(\mathbf{m}), \gamma_0(\mathbf{n}) \neq \emptyset$ , then
  - $\gamma_0(\mathbf{m}) = \gamma_0(\mathbf{n}) \iff \mathbf{m}^* =^\# \mathbf{n}^*$ ,
  - $\gamma_0(\mathbf{m}) \subseteq \gamma_0(\mathbf{n}) \iff \mathbf{m}^* \subseteq^\# \mathbf{n}^*$ .

## Floyd–Warshall algorithm

$$\begin{cases} m_{ij}^0 & \stackrel{\text{def}}{=} m_{ij} \\ m_{ij}^{k+1} & \stackrel{\text{def}}{=} \min(m_{ij}^k, m_{ik}^k + m_{kj}^k) \end{cases}$$

- If  $\gamma_0(\mathbf{m}) \neq \emptyset$ , then  $\mathbf{m}^* = \mathbf{m}^{n+1}$ , (normal form)
- $\gamma_0(\mathbf{m}) = \emptyset \iff \exists i: m_{ii}^{n+1} < 0$ , (emptiness testing)
- $\mathbf{m}^{n+1}$  can be computed in  $\mathcal{O}(n^3)$  time.

# Abstract operators

Abstract join: naive version  $\cup^\#$  (*element-wise max*)

- $\cup^\#$  is a **sound abstraction** of  $\cup$

but  $\gamma_0(\mathbf{m} \cup^\# \mathbf{n})$  is **not necessarily the smallest zone** containing  $\gamma_0(\mathbf{m})$  and  $\gamma_0(\mathbf{n})$  !

The union of two zones with  $\cup^\#$  is no more precise in the zone domain than in the interval domain!

# Abstract operators (cont.)

Abstract join: precise version:  $\cup^\sharp$  after closure

- $(\mathbf{m}^*) \cup^\sharp (\mathbf{n}^*)$  is however **optimal**

we have:  $(\mathbf{m}^*) \cup^\sharp (\mathbf{n}^*) = \min_{\subseteq^\sharp} \{ \mathbf{o} \mid \gamma_0(\mathbf{o}) \supseteq \gamma_0(\mathbf{m}) \cup \gamma_0(\mathbf{n}) \}$

which implies:

$$\gamma_0((\mathbf{m}^*) \cup^\sharp (\mathbf{n}^*)) = \min_{\subseteq} \{ \gamma_0(\mathbf{o}) \mid \gamma_0(\mathbf{o}) \supseteq \gamma_0(\mathbf{m}) \cup \gamma_0(\mathbf{n}) \}$$

after closure, new constraints  $c \leq X - Y \leq d$  give an increase in precision

- $(\mathbf{m}^*) \cup^\sharp (\mathbf{n}^*)$  is always closed.

# Abstract operators (cont.)

## Abstract intersection $\cap^\sharp$ : element-wise min

- $\cap^\sharp$  is an exact abstraction of  $\cap$  (zones are closed under intersection):

$$\gamma_0(\mathbf{m} \cap^\sharp \mathbf{n}) = \gamma_0(\mathbf{m}) \cap \gamma_0(\mathbf{n})$$

- $(\mathbf{m}^*) \cap^\sharp (\mathbf{n}^*)$  is not necessarily closed...

# Abstract operators (cont.)

We can define:

$$\left[ C^\# \llbracket V_{j_0} - V_{i_0} \leq c \rrbracket \mathbf{m} \right]_{ij} \stackrel{\text{def}}{=} \begin{cases} \min(m_{ij}, c) & \text{if } (i, j) = (i_0, j_0), \\ m_{ij} & \text{otherwise.} \end{cases}$$

$$\left[ C^\# \llbracket V_{j_0} \leftarrow [-\infty, +\infty] \rrbracket \mathbf{m} \right]_{ij} \stackrel{\text{def}}{=} \begin{cases} +\infty & \text{if } i = j_0 \text{ or } j = j_0, \\ m_{ij}^* & \text{otherwise.} \end{cases}$$

not optimal on non-closed arguments

$$C^\# \llbracket V_{j_0} \leftarrow V_{i_0} + a \rrbracket \mathbf{m} \stackrel{\text{def}}{=} (C^\# \llbracket V_{j_0} - V_{i_0} = a \rrbracket \circ C^\# \llbracket V_{j_0} \leftarrow [-\infty, +\infty] \rrbracket) \mathbf{m} \quad \text{if } i_0 \neq j_0$$

$$\left[ C^\# \llbracket V_{j_0} \leftarrow V_{j_0} + a \rrbracket \mathbf{m} \right]_{ij} \stackrel{\text{def}}{=} \begin{cases} m_{ij} - a & \text{if } i = j_0 \text{ and } j \neq j_0 \\ m_{ij} + a & \text{if } i \neq j_0 \text{ and } j = j_0 \\ m_{ij} & \text{otherwise.} \end{cases}$$

These transfer functions are **exact**.

# Abstract operators (cont.)

Backward assignment:

$$\overleftarrow{C}^\# \llbracket V_{j_0} \leftarrow [-\infty, +\infty] \rrbracket (m, r) \stackrel{\text{def}}{=} m \cap^\# (C^\# \llbracket V_{j_0} \leftarrow [-\infty, +\infty] \rrbracket r)$$

$$\overleftarrow{C}^\# \llbracket V_{j_0} \leftarrow V_{j_0} + a \rrbracket (m, r) \stackrel{\text{def}}{=} m \cap^\# (C^\# \llbracket V_{j_0} \leftarrow V_{j_0} - a \rrbracket r)$$

$$\left[ \overleftarrow{C}^\# \llbracket V_{j_0} \leftarrow V_{j_0} + a \rrbracket (m, r) \right]_{ij} \stackrel{\text{def}}{=} m \cap^\# \begin{cases} \min(r_{ij}^*, r_{j_0j}^* + a) & \text{if } i = i_0 \text{ and } j \neq i_0, j_0 \\ \min(r_{ij}^*, r_{ij_0}^* - a) & \text{if } j = i_0 \text{ and } i \neq i_0, j_0 \\ +\infty & \text{if } i = j_0 \text{ or } j = j_0 \\ r_{ij}^* & \text{otherwise.} \end{cases}$$

# Abstract operators (cont.)

**Issue:** given an arbitrary linear assignment  $V_{j_0} \leftarrow a_0 + \sum_k a_k \times V_k$

- there is no exact abstraction in general,
- the best abstraction  $\alpha \circ C \llbracket c \rrbracket \circ \gamma$  can be costly to compute.  
(e.g. convert to a polyhedron and back, with exponential cost)

## Possible solution:

Given a (more general) assignment  $e = [a_0, b_0] + \sum_k [a_k, b_k] \times V_k$ ,  
we define an **approximate** operator as follows:

$$[C^\sharp \llbracket V_{j_0} \leftarrow e \rrbracket \mathbf{m}]_{ij} \stackrel{\text{def}}{=} \begin{cases} \max(E^\sharp \llbracket e \rrbracket \mathbf{m}) & \text{if } i = 0 \text{ and } j = j_0 \\ -\min(E^\sharp \llbracket e \rrbracket \mathbf{m}) & \text{if } i = j_0 \text{ and } j = 0 \\ \max(E^\sharp \llbracket e - V_i \rrbracket \mathbf{m}) & \text{if } i \neq 0, j_0 \text{ and } j = j_0 \\ -\min(E^\sharp \llbracket e + V_j \rrbracket \mathbf{m}) & \text{if } i = j_0 \text{ and } j \neq 0, j_0 \\ m_{ij} & \text{otherwise} \end{cases}$$

where  $E^\sharp \llbracket e \rrbracket \mathbf{m}$  evaluates  $e$  using interval arithmetics with  $V_k \in [-m_{k0}^*, m_{0k}^*]$ .

**Quadratic** total cost (plus the cost of closure).

# Abstract operators (cont.)

## Example:

Argument

$$\begin{cases} 0 \leq Y \leq 10 \\ 0 \leq Z \leq 10 \\ 0 \leq Y - Z \leq 10 \end{cases}$$

$$\Downarrow X \leftarrow Y - Z$$

$$\begin{cases} -10 \leq X \leq 10 \\ -20 \leq X - Y \leq 10 \\ -20 \leq X - Z \leq 10 \end{cases}$$

Intervals

$$\begin{cases} -10 \leq X \leq 10 \\ -10 \leq X - Y \leq 0 \\ -10 \leq X - Z \leq 10 \end{cases}$$

Approximate  
solution

$$\begin{cases} 0 \leq X \leq 10 \\ -10 \leq X - Y \leq 0 \\ -10 \leq X - Z \leq 10 \end{cases}$$

Best  
(polyhedra)

We have a good trade-off between cost and precision.

The same idea can be used for tests and backward assignments.

# Widening and narrowing

The zone domain has both strictly increasing and decreasing infinite chains.

Widening  $\nabla$ :

$$[m \nabla n]_{ij} \stackrel{\text{def}}{=} \begin{cases} m_{ij} & \text{if } n_{ij} \leq m_{ij} \\ +\infty & \text{otherwise} \end{cases}$$

Unstable constraints are deleted.

Narrowing  $\Delta$ :

$$[m \Delta n]_{ij} \stackrel{\text{def}}{=} \begin{cases} n_{ij} & \text{if } m_{ij} = +\infty \\ m_{ij} & \text{otherwise} \end{cases}$$

Only  $+\infty$  bounds are refined.

Remarks:

- We can construct widenings with thresholds.
- $\nabla$  (resp.  $\Delta$ ) can be seen as a **point-wise extension** of an interval widening (resp. narrowing).

# Interaction between closure and widening

Widening  $\nabla$  and closure  $*$  cannot always be mixed safely:

- $\mathbf{m}_{i+1} \stackrel{\text{def}}{=} \mathbf{m}_i \nabla (\mathbf{n}_i^*)$  OK
- $\mathbf{m}_{i+1} \stackrel{\text{def}}{=} (\mathbf{m}_i^*) \nabla \mathbf{n}_i$  wrong!
- $\mathbf{m}_{i+1} \stackrel{\text{def}}{=} (\mathbf{m}_i \nabla \mathbf{n}_i)^*$  wrong

Otherwise the sequence  $(\mathbf{m}_i)$  may be infinite.

Example:

```

X ← 0; Y ← [-1,1];
while ● 1 = 1 do
  R ← [-1,1];
  if X = Y then Y ← X + R
  else X ← Y + R fi
done

```

iter.	X	Y	X - Y
0	0	[-1, 1]	[-1, 1]
1	[-2, 2]	[-1, 1]	[-1, 1]
2	[-2, 2]	[-3, 3]	[-1, 1]
...	...	...	...
2j	[-2j, 2j]	[-2j - 1, 2j + 1]	[-1, 1]
2j + 1	[-2j - 2, 2j + 2]	[-2j - 1, 2j + 1]	[-1, 1]

Applying the closure after the widening at ● prevents convergence.

Without the closure, we would find in finite time  $X - Y \in [-1, 1]$ .

Note: this situation also occurs in **reduced products**.

(here,  $\mathcal{D}^\# \simeq$  reduced product of  $n \times n$  intervals,  $*$   $\simeq$  reduction)

# Interaction between closure and widening (illustration)

```

X ← 0; Y ← [-1,1];
while • 1 = 1 do
  R ← [-1,1];
  if X = Y then Y ← X + R
  else X ← Y + R fi
done

```

iter.	X	Y	X - Y
0	0	$[-1, 1]$	$[-1, 1]$
1	$[-2, 2]$	$[-1, 1]$	$[-1, 1]$
2	$[-2, 2]$	$[-3, 3]$	$[-1, 1]$
...	...	...	...
$2j$	$[-2j, 2j]$	$[-2j - 1, 2j + 1]$	$[-1, 1]$
$2j + 1$	$[-2j - 2, 2j + 2]$	$[-2j - 1, 2j + 1]$	$[-1, 1]$

# Octagon domain

---

# The octagon domain

Now,  $\mathbb{I} \in \{\mathbb{Q}, \mathbb{R}\}$ .

We look for invariants of the form:  $\bigwedge \pm V_i \pm V_j \leq c, \quad c \in \mathbb{I}.$

A subset of  $\mathbb{I}^n$  defined by such constraints is called an **octagon**.

It is a generalization of zones (more symmetric).

[Miné01b]

# Machine representation

**Idea:** use a **variable change** to get back to potential constraints.

Let  $\mathbb{V}' \stackrel{\text{def}}{=} \{V'_1, \dots, V'_{2n}\}$ .

The constraint	is encoded as
$V_i - V_j \leq c \quad (i \neq j)$	$V'_{2i-1} - V'_{2j-1} \leq c \quad \text{and} \quad V'_{2j} - V'_{2i} \leq c$
$V_i + V_j \leq c \quad (i \neq j)$	$V'_{2i-1} - V'_{2j} \leq c \quad \text{and} \quad V'_{2j-1} - V'_{2i} \leq c$
$-V_i - V_j \leq c \quad (i \neq j)$	$V'_{2j} - V'_{2i-1} \leq c \quad \text{and} \quad V'_{2i} - V'_{2j-1} \leq c$
$V_i \leq c$	$V'_{2i-1} - V'_{2i} \leq 2c$
$V_i \geq c$	$V'_{2i} - V'_{2i-1} \leq -2c$

We use a matrix  $\mathbf{m}$  of size  $(2n) \times (2n)$  with elements in  $\mathbb{I} \cup \{+\infty\}$  and

$\gamma_{\pm}(\mathbf{m}) \stackrel{\text{def}}{=} \{ (v_1, \dots, v_n) \mid (v_1, -v_1, \dots, v_n, -v_n) \in \gamma(\mathbf{m}) \}$ .

Note:

Two distinct  $\mathbf{m}$  elements can represent the same constraint on  $\mathbb{V}$ .

To avoid this, we impose that  $\forall i, j: m_{ij} = m_{\bar{j} \bar{i}}$  where  $\bar{i} = i \oplus 1$ .

# Machine representation (cont.)

## Example:

$$\left\{ \begin{array}{l} V_1 + V_2 \leq 3 \\ V_2 - V_1 \leq 3 \\ V_1 - V_2 \leq 3 \\ -V_1 - V_2 \leq -3 \\ 2V_2 \leq 2 \\ -2V_2 \leq 8 \end{array} \right.$$

**Lattice :** constructed by point-wise extension of  $\leq$  on  $\mathbb{I} \cup \{+\infty\}$ .

# Algorithms

$\mathbf{m}^*$  is not a normal form for  $\gamma_{\pm}$ .

**Idea** use **two** local transformations instead of one:

$$\left\{ \begin{array}{l} V'_i - V'_k \leq c \\ V'_k - V'_j \leq d \end{array} \right\} \implies V'_i - V'_j \leq c + d$$

and

$$\left\{ \begin{array}{l} V'_i - V'_j \leq c \\ V'_j - V'_j \leq d \end{array} \right\} \implies V'_i - V'_j \leq (c + d)/2$$

## Modified Floyd–Warshall algorithm:

$$\mathbf{m}^{\bullet} \stackrel{\text{def}}{=} S(\mathbf{m}^{2n+1})$$

where:

$$(A) \quad \left\{ \begin{array}{l} \mathbf{m}^1 \stackrel{\text{def}}{=} \mathbf{m} \\ [\mathbf{m}^{k+1}]_{ij} \stackrel{\text{def}}{=} \min(n_{ij}, n_{ik} + n_{kj}), \quad 1 \leq k \leq 2n \end{array} \right.$$

$$(B) \quad [S(\mathbf{n})]_{ij} \stackrel{\text{def}}{=} \min(n_{ij}, (n_{i\bar{i}} + n_{\bar{j}j})/2)$$

# Algorithms (cont.)

## Applications:

- $\gamma_{\pm}(\mathbf{m}) = \emptyset \iff \exists i: \mathbf{m}_{ii}^{\bullet} < 0$ ,
- if  $\gamma_{\pm}(\mathbf{m}) \neq \emptyset$ ,  $\mathbf{m}^{\bullet}$  is a normal form:  
$$\mathbf{m}^{\bullet} = \min_{\subseteq^{\#}} \{ \mathbf{n} \mid \gamma_{\pm}(\mathbf{n}) = \gamma_{\pm}(\mathbf{m}) \},$$
- $(\mathbf{m}^{\bullet}) \cup^{\#} (\mathbf{n}^{\bullet})$  is the best abstraction for the set-union  $\gamma_{\pm}(\mathbf{m}) \cup \gamma_{\pm}(\mathbf{n})$ .

## Widening and narrowing:

- The zone widening and narrowing can be used on octagons.
- The widened iterates should not be closed. (prevents convergence)

Abstract transfer functions are similar to the case of the zone domain.

# Analysis example

## Rate limiter

```

Y ← 0; while 1=1 do
  X ← [-128,128]; D ← [0,16];
  S ← Y; Y ← X; R ← X - S;
  if R ≤ -D then Y ← S - D fi;
  if R ≥ D then Y ← S + D fi
done

```

X: input signal  
 Y: output signal  
 S: last output  
 R: delta  $Y - S$   
 D: max. allowed for  $|R|$

Analysis using:

- the octagon domain,
- an abstract operator for  $V_{j_0} \leftarrow [a_0, b_0] + \sum_k [a_k, b_k] \times V_k$  similar to the one we defined on zones,
- a widening with thresholds  $T$ .

**Result:** we prove that  $|Y|$  is bounded by:  $\min \{ t \in T \mid t \geq 144 \}$ .

**Note:** the polyhedron domain would find  $|Y| \leq 128$  and does not require thresholds, but it is more costly.

# Summary

---

# Summary of numerical domains

domain	invariants	memory cost	time cost (per operation)
intervals	$V \in [\ell, h]$	$\mathcal{O}( n )$	$\mathcal{O}( n )$
linear equalities	$\sum_i \alpha_i V_i = \beta_i$	$\mathcal{O}( n ^2)$	$\mathcal{O}( n ^3)$
zones	$V_i - V_j \leq c$	$\mathcal{O}( n ^2)$	$\mathcal{O}( n ^3)$
polyhedra	$\sum_i \alpha_i V_i \geq \beta_i$	unbounded, exponential in practice	

- abstract domains provide trade-offs between cost and precision
- relational invariants are often necessary  
even to prove non-relational properties
- an abstract domain is defined by the choice of:
  - some properties of interest and semantic operators *(semantic part)*
  - data-structures and algorithms to implement them *(algorithmic part)*
- an analysis mixes two kinds of approximations:
  - static approximations *(choice of abstract properties)*
  - dynamic approximations *(widening)*
